

Chapters 3, 4: Inference and Prediction

Reading: 3.1, 3.2, 3.5, 4.1, 4.2, 4.4

Inference

- Estimates: $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_p$
- Draw conclusions about $\beta_0, \beta_1, \dots, \beta_p$
- Two main inference tools:
 - hypothesis tests
 - confidence intervals

Savings Example

- 50 different countries
- Data from 1960 – 1970
- Response: aggregate personal savings divided by disposable income (sr)
- Predictors: per capital disposable income (dpi), percentage rate of change in per capita disposable income ($ddpi$), percentage of population under 15 ($pop15$), percentage of population over 75 ($pop75$)

```

> data(savings)
> savings

```

	sr	pop15	pop75	dpi	ddpi
Australia	11.43	29.35	2.87	2329.68	2.87
Austria	12.07	23.32	4.41	1507.99	3.93
...

```

> result <- lm(sr ~ pop15 + pop75 + dpi + ddpi,
  savings)

```

```
> summary(result)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	28.5660865	7.3545161	3.884	0.000334
pop15	-0.4611931	0.1446422	-3.189	0.002603
pop75	-1.6914977	1.0835989	-1.561	0.125530
dpi	-0.0003369	0.0009311	-0.362	0.719173
ddpi	0.4096949	0.1961971	2.088	0.042471

Residual standard error: 3.803 on 45 degrees of freedom

Multiple R-Squared: 0.3385, Adjusted R-squared: 0.2797

F-statistic: 5.756 on 4 and 45 DF, p-value: 0.0007904

Savings Example Ctd

- Is *pop75* significant in the full model?
- Estimated from data:

$$\begin{aligned}\hat{sr} = & 28.6 - 0.46 \times pop15 - 1.69 \times pop75 \\ & - 0.0003 \times dpi + 0.41 \times ddpi\end{aligned}$$

- Is “-1.69” random fluctuation due to chance, or does it indicate that the true coefficient β_{pop75} is different from 0?
- Each test only makes sense in the context of the fitted model

Hypothesis Tests

- Testing: use **probability** to decide whether data is consistent with hypothesis
- **Null** hypothesis H_0 (e.g. $\beta = 0$)
- **Alternative** hypothesis H_A (e.g. $\beta \neq 0$)
- Decide whether data is consistent with H_0 :
 - If not, **reject** H_0 and accept H_A
 - Otherwise, **fail to reject** H_0

Errors in Hypothesis Testing

		True State	
		H_0 true	H_0 false
Our Decision	Not reject H_0	✓	Type II error
	Reject H_0	Type I error	✓

The legal system analogy

- H_0 : The accused is innocent
- H_A : The accused is guilty
- Type I error: convict an innocent person
- Type II error: acquit a guilty person

Presumption of innocence:

- H_0 assumed true unless there is convincing evidence for H_A
- H_A carries the “burden of proof”

Procedure

- Set $\alpha = P(\text{type I error})$. Typically $\alpha = 0.05$ or 0.01 . α is called the **significance level**.
- Compute **p-value**: the probability of observed or more extreme departure from H_0 (in favor of H_A) when H_0 is true.
- If $p\text{-value} < \alpha$, reject H_0 .

Savings Example

Full model:

$$sr = \beta_0 + \beta_{pop15} \times pop15 + \beta_{pop75} \times pop75 + \beta_{dpi} \times dpi + \beta_{ddpi} \times ddpi$$

- Null hypothesis: $\beta_{pop75} = 0$
- Alternative hypothesis: $\beta_{pop75} \neq 0$

We observe that

$$\hat{sr} = 28.6 - 0.46 \times pop15 - 1.69 \times pop75 - 0.0003 \times dpi + 0.41 \times ddpi$$

Compute the p -value:

$$P(|\hat{\beta}_{pop75}| \geq 1.69 \mid \beta_{pop75} = 0)$$

Further Assumption on Errors

We have only assumed $E(\epsilon) = 0$. To compute the p -value, we also need to assume a **distribution** for the errors ϵ . The usual assumption is

$$\epsilon \sim \text{Normal}_n(0, \sigma^2 I)$$

Distribution of $\hat{\beta}$

If $\epsilon \sim N_n(0, \sigma^2 I)$, then

$$\begin{aligned}\hat{\beta} &\sim N_{p+1}(\beta, (X^T X)^{-1} \sigma^2) \\ \hat{\beta}_j &\sim N(\beta_j, (X^T X)^{-1}_{jj} \sigma^2)\end{aligned}$$

- The standard error is

$$se(\hat{\beta}_j) = \sqrt{(X^T X)^{-1}_{jj} \sigma^2}$$

- In practice, we use the **approximation**

$$\widehat{se}(\hat{\beta}_j) = \sqrt{(X^T X)^{-1}_{jj} \hat{\sigma}^2}$$

- Recall $\hat{\sigma}^2 = \frac{\sum_i (y_i - \hat{y}_i)^2}{n - (p+1)}$

Distribution of $\hat{\beta}$ Ctd

Under the normal assumption on the errors,

$$\frac{\hat{\beta}_j - \beta_j}{\text{se}(\hat{\beta}_j)} \sim N(0, 1)$$

$$\frac{\hat{\beta}_j - \beta_j}{\widehat{\text{se}}(\hat{\beta}_j)} \sim t_{n-(p+1)}$$

The t -distribution

Probability density function (pdf):

$$N(0, 1) \sim \frac{1}{\sqrt{2\pi}} e^{-1/2z^2}$$

$$t_n \sim \frac{\Gamma\left(\frac{n+1}{2}\right)}{\sqrt{n\pi} \cdot \Gamma\left(\frac{n}{2}\right)} (1 + z^2/n)^{-(n+1)/2}$$

- Has a single parameter n called **degrees of freedom**
- **Symmetric** around 0, “bell-shaped”, but heavier tails than normal
- As $n \rightarrow \infty$, $t_n \rightarrow N(0, 1)$

The t density

Like normal distribution with wider tails

The t -statistic (Savings Example)

If the null is true, i.e., $\beta_{pop75} = 0$, then

$$\frac{\hat{\beta}_{pop75}}{\widehat{se}(\hat{\beta}_{pop75})} \sim t_{50-(4+1)}$$

From the R output, we have (t -statistic)

$$\frac{\hat{\beta}_{pop75}}{\widehat{se}(\hat{\beta}_{pop75})} = -1.56$$

***t*-statistic (Savings Example) Ctd**

Is this value extreme for the t_{45} distribution? I.e., need to compute the the probability

$$P(\text{observe } "-1.56" \text{ or more extreme} | \beta_{pop75} = 0) = P(|t_{45}| \geq 1.56) = ?$$

What if the test is one-sided?

t -statistic (Savings Example) Ctd

t -test

- Two-sided test: $P(|t_{45}| \geq 1.56) = 0.13 > \alpha = 0.05$, therefore we fail to reject H_0 .
- Thus *pop75* is not significant in the full model at level $\alpha = 0.05$.
- ## CDF of t-distribution
 `> pt(1.56, df=45)`
 `[1] 0.937117`
 `> 2*(1 - pt(1.56, df=45))`
 `[1] 0.1257658`

Another (General) Approach

- Recall RSS : residual sum of squares $\sum_i \hat{\epsilon}_i^2$
- Fit a model under H_0 , compute RSS_{H_0} (e.g. with β_{pop75} set equal to 0)
- Fit another model under $H_0 \cup H_A$, compute $RSS_{H_0 \cup H_A}$ (e.g. no restriction on β_{pop75})
- Compute

$$F = \frac{(RSS_{H_0} - RSS_{H_0 \cup H_A}) / (df_{H_0} - df_{H_0 \cup H_A})}{RSS_{H_0 \cup H_A} / df_{H_0 \cup H_A}}$$

General Approach Ctd

- If H_0 is true,

$$F \sim F_{df_1, df_2}; \quad df_1 = df_{H_0} - df_{H_0 \cup H_A}, df_2 = df_{H_0 \cup H_A}$$

- Compute $p\text{-value} = P(F_{df_1, df_2} > F)$

F-distribution

- Z_1, \dots, Z_n i.i.d. $\text{Normal}(0,1)$. Then

$$U = Z_1^2 + \dots + Z_n^2$$

has χ^2 (chi-square) distribution with n degrees of freedom.

- χ_n^2 is the same as $\text{Gamma}(n/2, 2)$.
- Suppose $U \sim \chi_n^2$, $W \sim \chi_m^2$ are independent. Then

$$\frac{U/n}{W/m} \sim F_{n,m}$$

F-distribution with n and m degrees of freedom.

F-distribution

Important facts: (1) $F_{df_1, df_2} > 0$ (2) $t_{df}^2 \sim F_{1, df}$

F-test: Savings Example

```
## Model under H0  
> h0 <- lm(sr ~ pop15 + dpi + ddpi, savings)  
> summary(h0)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	19.2771687	4.3888974	4.392	6.53e-05
pop15	-0.2883861	0.0945354	-3.051	0.00378
dpi	-0.0008704	0.0008795	-0.990	0.32755
ddpi	0.3929355	0.1989390	1.975	0.05427

F-test: Savings Example

```
## Model under (H0 U HA)
> h0a <- lm(sr ~ pop15 + pop75 + dpi + ddpi, savings)
> anova(h0, h0a)
Analysis of Variance Table
```

Model 1: $sr \sim pop15 + dpi + ddpi$

Model 2: $sr \sim pop15 + pop75 + dpi + ddpi$

	Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
1	46	685.95				
2	45	650.71	1	35.24	2.4367	0.1255

F-test Ctd

***F*-test and *t*-test**

- $P(F_{1,45} > 2.44) = 0.13 > \alpha = 0.05$, therefore we fail to reject H_0 .
- Notice $t^2 = 1.56^2 = 2.44 = F$
- *F*-test and two-sided *t*-test are equivalent for testing a **single predictor**.

Test a Pair

- Whether both *pop75* and *dpi* can be excluded from the model.
- $H_0: \beta_{pop75} = \beta_{dpi} = 0$; H_A : not H_0 .

```
> h0 <- lm(sr ~ pop15 + ddpi, savings)
> h0a <- lm(sr ~ pop15 + pop75 + dpi + ddpi, savings)
> summary(h0)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	15.59958	2.33439	6.682	2.48e-08
pop15	-0.21638	0.06033	-3.586	0.000796
ddpi	0.44283	0.19240	2.302	0.025837

```
> anova(h0, h0a)
```

Analysis of Variance Table

Model 1: $sr \sim pop15 + ddp_i$

Model 2: $sr \sim pop15 + pop75 + dpi + ddp_i$

	Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
1	47	700.55				
2	45	650.71	2	49.84	1.7233	0.1900

- What if we want to test whether any of the predictors are useful in predicting the response?
- $H_0: \beta_{pop15} = \beta_{pop75} = \beta_{dpi} = \beta_{ddpi} = 0$

Test a Subspace

- Whether the effect of young people and the effect of old people on the savings rate are the same.
- $H_0: \beta_{pop15} = \beta_{pop75}$; $H_A: \beta_{pop15} \neq \beta_{pop75}$

```
> h0 <- lm(sr ~ I(pop15 + pop75) + dpi + ddpi, savings)
> h0a <- lm(sr ~ pop15 + pop75 + dpi + ddpi, savings)
> summary(h0)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	21.6093051	4.8833633	4.425	5.87e-05
I(pop15 + pop75)	-0.3336331	0.1038679	-3.212	0.00241
dpi	-0.0008451	0.0008444	-1.001	0.32212
ddpi	0.3909649	0.1968714	1.986	0.05302

Residual standard error: 3.827 on 46 degrees of freedom
Multiple R-Squared: 0.3152, Adjusted R-squared: 0.2705
F-statistic: 7.056 on 3 and 46 DF, p-value: 0.0005328

```
> anova(h0, h0a)
```

Analysis of Variance Table

Model 1: $sr \sim I(\text{pop15} + \text{pop75}) + \text{dpi} + \text{ddpi}$

Model 2: $sr \sim \text{pop15} + \text{pop75} + \text{dpi} + \text{ddpi}$

	Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
1	46	673.63				
2	45	650.71	1	22.91	1.5847	0.2146

Test another Subspace

- Test whether β_{ddpi} is equal to 0.5
- $H_0: \beta_{ddpi} = 0.5$; $H_A: \beta_{ddpi} \neq 0.5$

```
> h0 <- lm(sr ~ pop15 + pop75 + dpi + offset(0.5*ddpi),  
  savings)  
> summary(h0)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	27.9287866	7.1608589	3.900	0.000311
pop15	-0.4543714	0.1426430	-3.185	0.002596
pop75	-1.7187908	1.0726662	-1.602	0.115923
dpi	-0.0002274	0.0008925	-0.255	0.800004

```
> h0a <- lm(sr ~ pop15 + pop75 + dpi + ddpi, savings)
> anova(h0, h0a)
```

Analysis of Variance Table

Model 1: $sr \sim pop15 + pop75 + dpi + offset(0.5 * ddpi)$

Model 2: $sr \sim pop15 + pop75 + dpi + ddpi$

	Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
1	46	653.78				
2	45	650.71	1	3.06	0.2119	0.6475

- What about using *t*-test?

Confidence Intervals

Why do we care about CI?

- Hypothesis test: yes/no only
- Dependence on sample size
- Statistical significance vs. practical significance

Confidence Intervals for β_j

Consider each parameter individually.

$$\text{Recall } \frac{\hat{\beta}_j - \beta_j}{\widehat{\text{se}}(\hat{\beta}_j)} \sim t_{n-(p+1)}$$

Hence

$$P\left(-t_{n-(p+1)}^{(\alpha/2)} \leq \frac{\hat{\beta}_j - \beta_j}{\widehat{\text{se}}(\hat{\beta}_j)} \leq t_{n-(p+1)}^{(\alpha/2)}\right) = 1 - \alpha$$

Or with probability $1 - \alpha$, i.e. confidence $100(1 - \alpha)\%$

$$\hat{\beta}_j - t_{n-(p+1)}^{(\alpha/2)} \cdot \widehat{\text{se}}(\hat{\beta}_j) \leq \beta_j \leq \hat{\beta}_j + t_{n-(p+1)}^{(\alpha/2)} \cdot \widehat{\text{se}}(\hat{\beta}_j)$$

$t^{(\alpha)}$ is the **tail probability**: $P(t > t^{(\alpha)}) = \alpha$.

Confidence Intervals for β_j Ctd

- General form:

estimate \pm critical value \times s.e. of estimate

- Two-sided t -test and CI

Savings Example

```
> result <- lm(sr ~ pop15 + pop75 + dpi + ddpi, savings)
> summary(result)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	28.5660865	7.3545161	3.884	0.000334
pop15	-0.4611931	0.1446422	-3.189	0.002603
pop75	-1.6914977	1.0835989	-1.561	0.125530
dpi	-0.0003369	0.0009311	-0.362	0.719173
ddpi	0.4096949	0.1961971	2.088	0.042471

Savings Example

```
## Convenient way to compute CIs
```

```
> conf <- confint(result)
```

```
> conf
```

	2.5 %	97.5 %
(Intercept)	13.753330728	43.378842354
pop15	-0.752517542	-0.169868752
pop75	-3.873977955	0.490982602
dpi	-0.002212248	0.001538444
ddpi	0.014533628	0.804856227

Simultaneous Confidence Regions

Similarly,

$$\frac{(\hat{\beta} - \beta)^T X^T X (\hat{\beta} - \beta)}{(p+1)\hat{\sigma}^2} \sim F_{p+1, n-(p+1)}$$

With probability $1 - \alpha$, i.e. confidence $100(1 - \alpha)\%$

$$(\hat{\beta} - \beta)^T X^T X (\hat{\beta} - \beta) \leq (p+1)\hat{\sigma}^2 F_{p+1, n-(p+1)}^{(\alpha)}$$

Savings Example

```
## Need to install the "ellipse" package
> library(ellipse)
## Plot the confidence region
> plot(ellipse(result, c('pop15', 'pop75')),
      type=="l", xlim=c(-1,0))
## Add the estimates to the plot
> points(result$coef['pop15'], result$coef['pop75'], pch=18)
## Add the origin to the plot
> points(0, 0, pch=1)
## Add the confidence interval for pop15
> abline(v=conf['pop15',], lty=2)
## Add the confidence interval for pop75
> abline(h=conf['pop75',], lty=2)
```

Savings Example: Confidence region

```
## Correlation between pop15 and pop75  
> plot(x=savings$pop15, y=savings$pop75)  
> cor(savings$pop15, savings$pop75)  
[1] -0.9084787
```

Correlation between predictors

Confidence Intervals for Predictions

- Given new predictors, x_0 , what is the predicted response?

$$\hat{y}_0 = x_0^T \hat{\beta}$$

- Two types of predictions:
 - Prediction of a **future observation**
 - Prediction of the **future mean response**
- Prediction intervals vs. confidence intervals

Confidence Intervals for Predictions Ctd

For a future observation:

$$\hat{y}_0 \pm t_{n-(p+1)}^{(\alpha/2)} \hat{\sigma} \sqrt{1 + x_0^T (X^T X)^{-1} x_0}$$

For the future mean response:

$$\hat{y}_0 \pm t_{n-(p+1)}^{(\alpha/2)} \hat{\sigma} \sqrt{x_0^T (X^T X)^{-1} x_0}$$

Savings Example

```
> result <- lm(sr ~ pop15 + pop75 + dpi + ddpi, savings)
## Convenient way to compute CI and PI
> x0 <- data.frame(pop15=35, pop75=2, dpi=1000, ddpi=4)
> predict(result, x0, interval="confidence")
           fit          lwr          upr
[1,] 10.34321  9.093452 11.59297
> predict(result, x0, interval="prediction")
           fit          lwr          upr
[1,] 10.34321  2.582946 18.10347
```

```
## Generate a sequence of points
> grid <- seq(20, 60, 1)
> pred <- predict(result, data.frame(pop15=grid, pop75=2,
  dpi=1000, ddpi=4), interval="confidence")
## Plot a matrix
> matplot(grid, pred, lty=c(1,2,2), col=1, type="l",
  xlab="pop15", ylab="sr")
> rug(savings$pop15)
```

Prediction Band Plot
